# SIP Resume

- Professional Civil Engineer (CA, NV, OR, UT, AZ, MD, NM, TN, & TX)
- Bachelor's & Master's in Mechanical Engineering  
Cal Poly, San Luis Obispo & Stanford University
- Designing with SIPs since 2017  
Engineering in California since 2008
- Member of SIPA (Structural Insulated Panel Association)

# PRESENTATION ROADMAP

- Review of Structural Insulated Panels
- How Can Architects Design for SIPs?
- What Can SIPs Do for Architects?
- 10 Common SIP Structural Engineering Mistakes
- Building a SIPs Structure
- SIPs and Energy

# Review of Structural Insulated Panels

# What is a SIP?

7/16" Oriented Strand Board (OSB)

Expanded Polystyrene  
Foam Core (2x width)

7/16" Oriented Strand Board (OSB)

3-1/2"

5-1/2"

7-1/4"

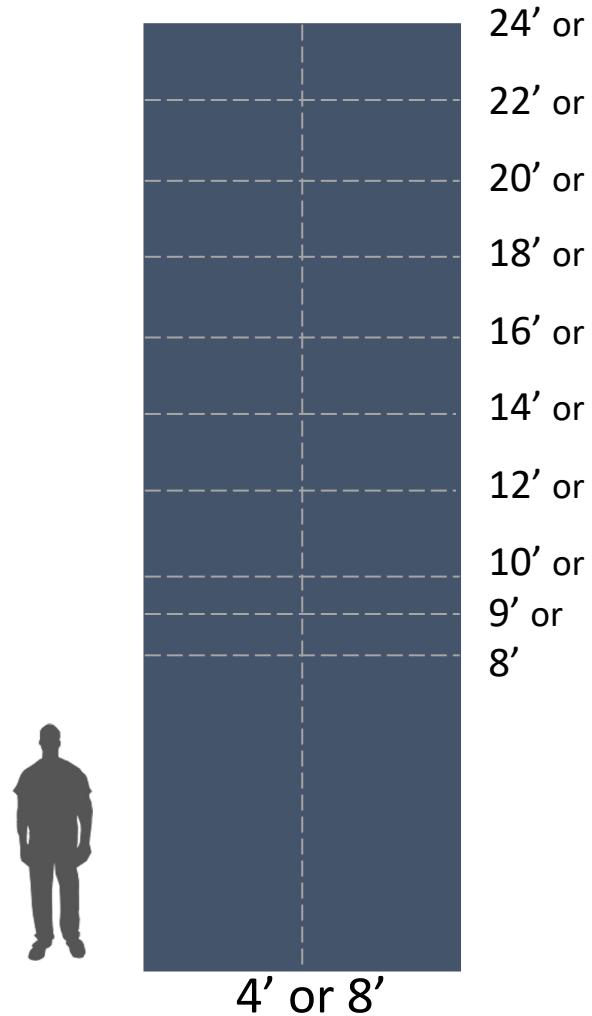

9-1/4"

11-1/4"

# How big is a SIP?

Note: SIP skins are a single piece of OSB.

# What can a SIP do?

- Replace Exterior Walls, Floors, Roofs
- Support Vertical Loads in Walls
- Support Transverse Loads (Wind against wall, Gravity Loads on Roofs and Floors)
- Support In-Plane Loads (Shear Walls and Diaphragms)
- Provide an Exceptional Environmental Envelope
- Provide Straight and Rigid Walls
- Provide Faster Construction Schedule

# How do SIPs attach together?

Panels – with splines

TYPE S SPLINE

TYPE I SPLINE

TYPE L SPLINE

Corners – with SIP screws

# How do SIPs make a house?

SIP manufacturer:

- Receives plans
- Creates shop drawings showing each type of panel and its location
- Fabricates the panels per plan

# How do SIPs make a house?

# How strong are SIPs?

2 tons of uniform load

1 ton of point load

# How Can Architects Design for SIPs?

# Structure Design

## Plate Heights

- Use standard heights to avoid excess material/assembly time

## Wall Lengths

- Keep 4' and 8' lengths in mind to save material and splines

24' or  
22' or  
20' or  
18' or  
16' or  
14' or  
12' or  
10' or  
9' or  
8'

4' or 8'

How Can Architects Design for SIPs?

# HVAC Best Practices

- Consider duct locations
- Dropped ceilings in bathrooms, closets, and hallways
- Soffits to access remaining parts of the structure
- Account for returns

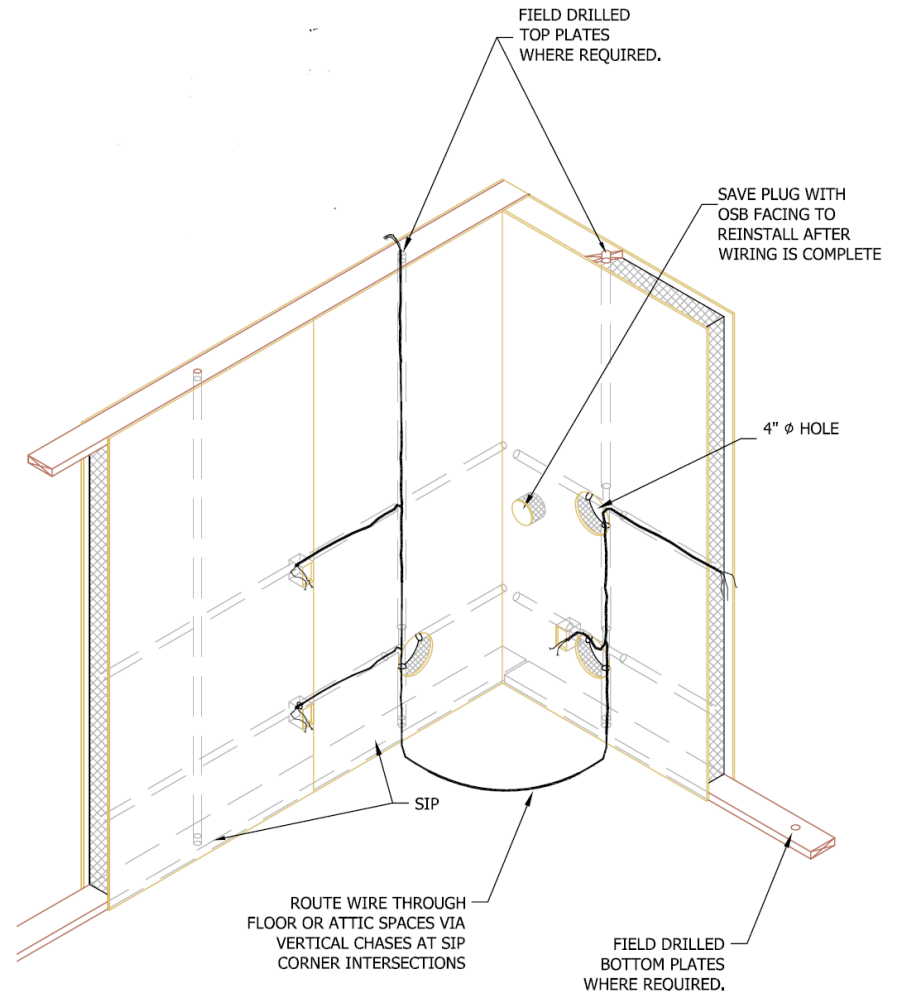

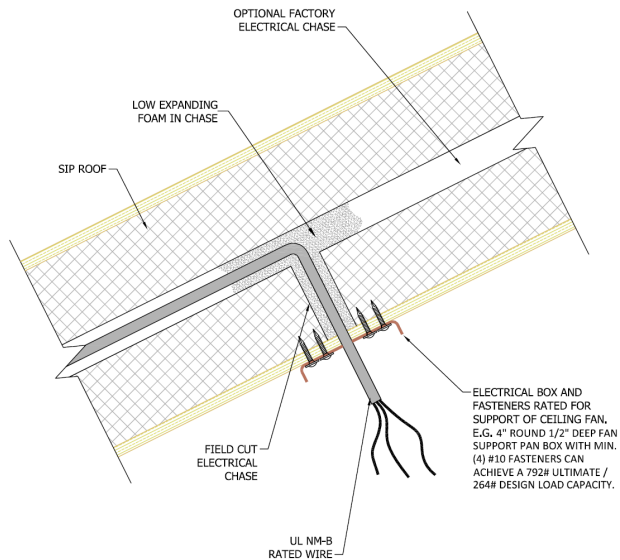

# Plumbing Considerations

- Drill a hole through the SIP for water/gas lines
- Furring is a design option
- Never place plumbing lines in exterior walls
- Water lines cannot run inside a SIP wall

# Electrical Considerations

- SIPs come with electrical chases
- Use 2X4 flush ceiling for recessed lighting
- SES can be surface mounted
- Can design SIPs around the SES

# What Can SIPs Do for Architects?

# Cathedral Ceilings

SIP Advantages:

- Long spans
- Avoid drywall sag and cracking
- 8' plate height is a base for a tall ceiling feel

What Can SIPs do for Architects?

# Long Overhangs

SIPs can cantilever up to 12'

- Must check loading

# Wall Thickness Variation

- Wall thickness does not necessarily affect cost
- Double plumbing wall adds architectural flare in kitchens and bathrooms
- Can play with recesses
  - 12" thick wall with 8" recessed window
  - Special order thicker panels for a more dramatic recess

# Corner Window Options

Need (2) “L” or “C” shaped panels

- No headers, no steel required
- No back-spans
- Just design it in!

# 10 Common SIP Structural Engineering Mistakes

# 1 – Double Lumber Splines

## Characteristics

- Two 2x's nailed together
- Not straight
- “Through” joist created
- Thermal bridge created – R value similar to stick framing
- ICC requires this at 4'-0”
- Need to drill for electrical
- Vertical and transverse capacity of 10'-6” SIP by ~50%
- Typical wind force <30 psf
- Adds material and labor cost

# 1 – Double Lumber Splines

## Concerns

- 2x's will expand and contract with temperature changes
- Air will leak
- Once the “through” joist opens, does not close
- Nails in “pull out” position with little resistance
- Stucco and drywall will crack
- Placing (2) 2x's at 48" is just like placing (1) 2x at 24"

# 1 – Double Lumber Splines

Alternatives:

I Spline

S Spline

Post

## 2 – Shear Walls

### Conventional Framing

- Almost always designed as distinct shear panels
- Each shear panel acts alone
- Requires hold downs and extra lumber

## 2 – Shear Walls

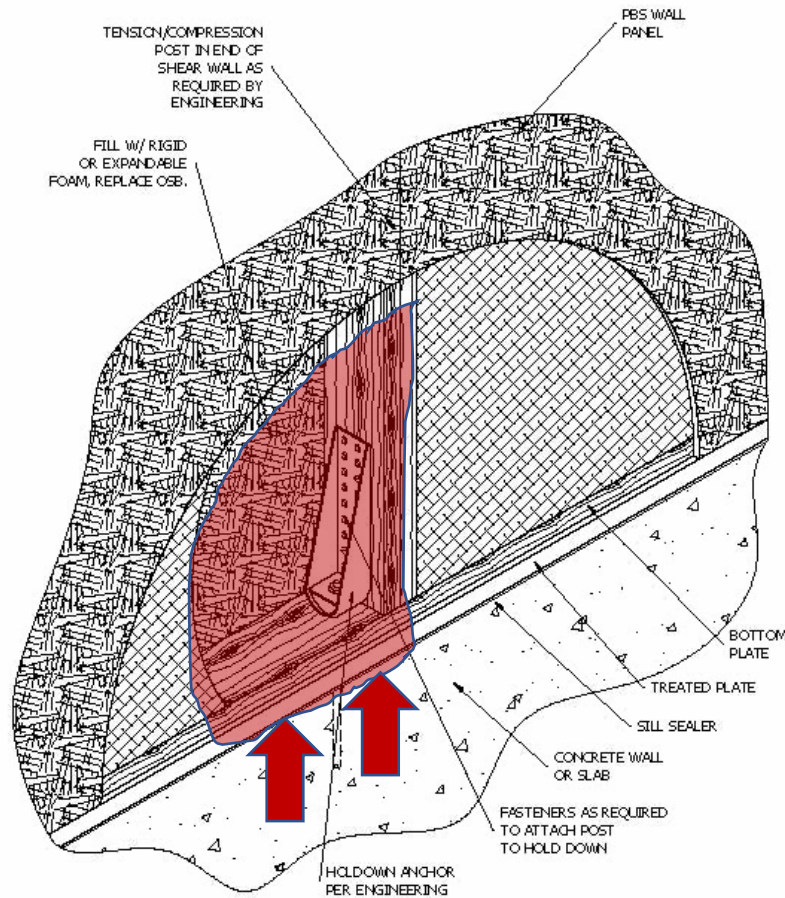

SIPs

- Act as a rigid diaphragm for the entire length of the wall
- Design your SIP as perforated shearwall

# 3 – Hold Downs

## HDU Hold Down – Time/Cost

## Strap Hold Down – More Efficient

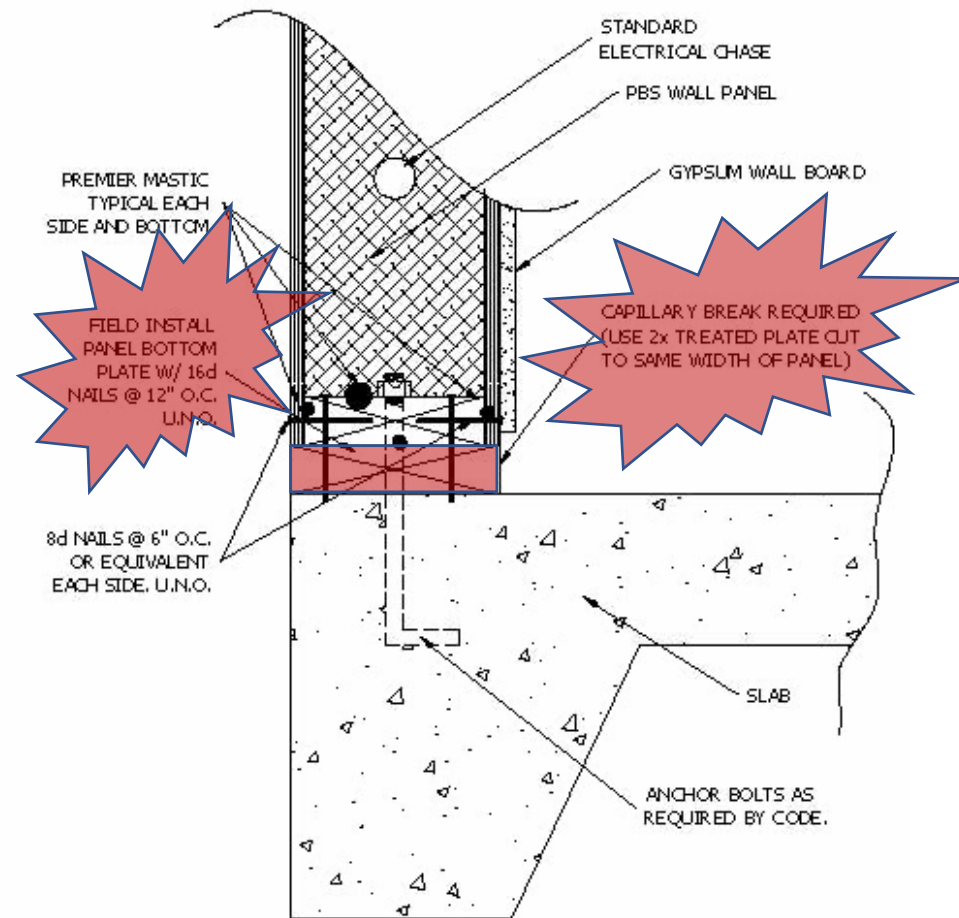

## 4 – Sill Plates

## 4 – Sill Plates

## 4 – Sill Plates

# 5 – Top Plate Options

## Single Top Plate

- Typical condition
- Used in testing
- No splices
- Less lumber
- Less labor

## Double Top Plate

- Not typical
- For higher strength shear
- No splices
  - offset
- More lumber
- More labor

## Cap Plate

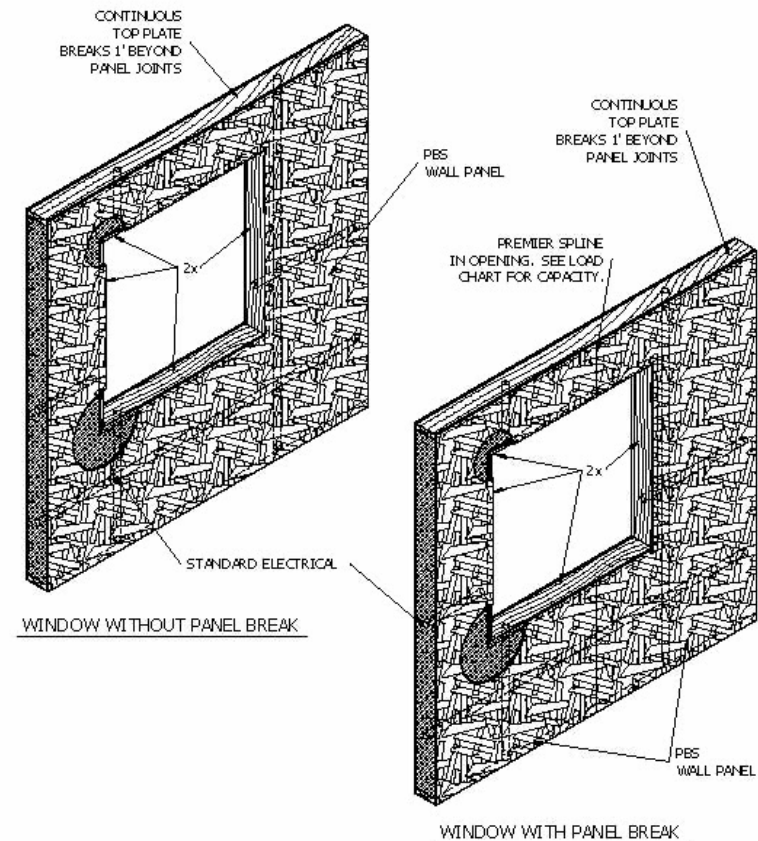

- 2x must be ripped to wall width – expensive
- Creates thermal bridging
- Increases wall allowable point load from 1 ton to 2 tons

## 6.1 – Panel Headers

SIP panel often supports the loads

- Do not need a header for the opening
- Factory cut opening into the panel
- Site build an opening with panels
- No trimmers

## 6.2 – Insulated Headers

- For larger spans and/or heavy loads
- Usually placed at top of wall
- Require trimmers
- Several parts to assemble
- Hinge created
- Skins must bear on beam
- Place header inside SIP to save cost
- Nails used for shear
  - Staggered rows of (4) 16d nails at 6" o.c. carry high loads

## 7 – King Studs

- Transfer load from wall above to walls beside an opening
- With SIPs, king studs have no load
  - SIP walls use the skin
- Therefore, no king studs required in most SIP applications

## 8 – Beam Pockets

- Most beams just need a pocket (no post-2450# capacity)
- Add post if necessary
- In a few cases, need a strap- no bucket necessary

## 9 – Columns / Posts

### Conventional Framing

- Load goes straight down the post
- Point load for next level down

### SIPs

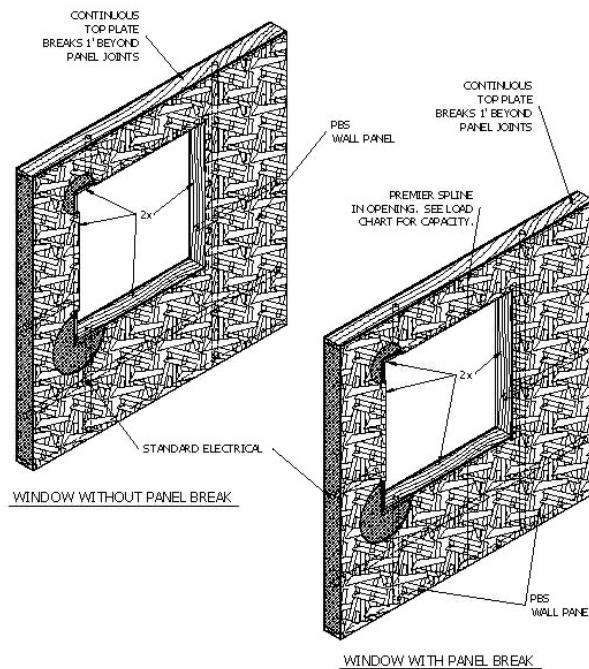

- Load distributed through the skin (like a CMU wall)
- Linear load for next level down

# 10 - Framing

## Conventional Framing

- Every opening has a header  
Time and labor to frame

## SIPs

- Most openings do not need headers
- Designing such that larger loads fall on smaller openings could mean no headers needed

# Building a SIPs Structure

# 1 – Organization

Before the panels arrive:

- Install and inspect sill plate
- Mark sill plate with panel numbers
- Decide which corner you will start with (back is best)

Before construction begins:

- Sort the panels – they arrive on the truck based on what fits best
- Create stacks of 4-5 panels in order of installation
- Have permit and shop drawings on the jobsite for reference

## 2 – 5-Person Crew

### Walls

- 2 people installing panels
- 2 people preparing the next panel for installation
- 1 person getting mastic, cutting helping lift, etc.

### Roof

- 2 people installing panels
- 2 people preparing the next panel for installation
- 1 driver/helper

### 3 – Wall Installation

- Can slide panels instead of carrying them
- Tilt and slide panels together
- Drop panels into place
- Install corner screws as panels are installed
- Plumb and level corners, checking every few panels
- Minimal to no bracing

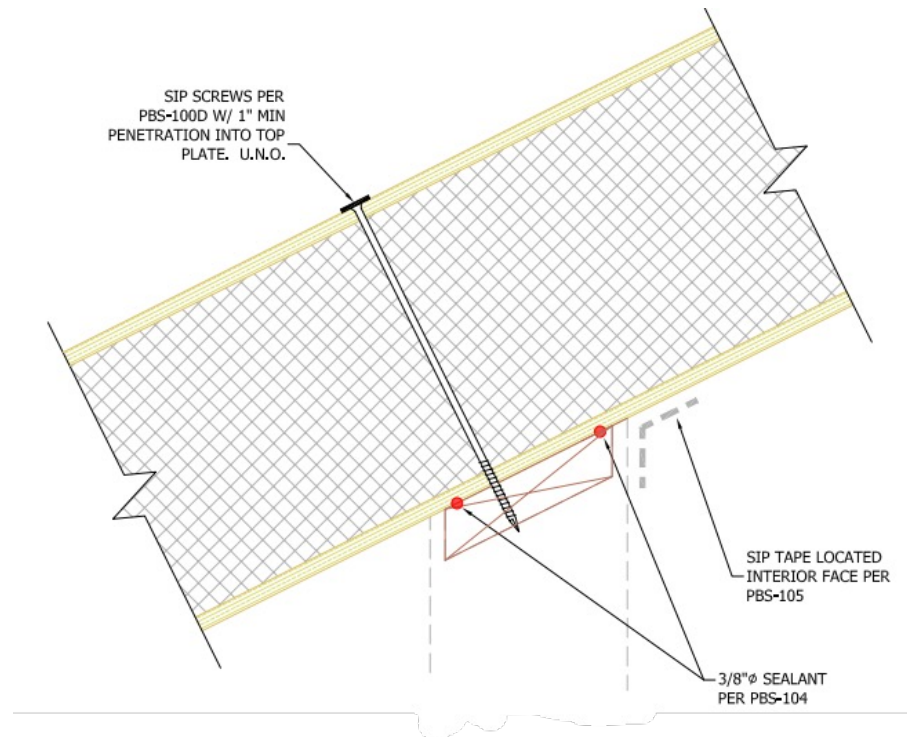

Conventional Wall

SIP Wall

## 4 – Roof Installation

- Use rigging for first few panels
- Can use panels as a staging area
- Slide instead of carrying panels
- Use furniture dollies to carry them across the roof
- Start at one corner, nail, slide in the other corner
- Double nail the top if underside is inaccessible

## 5 – Top Plates / Bucks

- Wall Top Plates come last (after electrician)
- Filler work
- Top and bottom plates cut 3" wider than the opening, 1.5" each side
- Remember the mastic / glue

## 6 - Stucco

- No Styrofoam
  - House paper – lath – scratch coat – final coat
- 50% more staples
- Should save on labor time/cost

## 7 - Drywall

- Use full sheets on exterior walls
  - No trimming to match studs
- Simple 12" o.c. screw pattern
- Can use ¼", ½", or 5/8" GWB

## 8 - Electrical

- Horizontal chases are at outlet and switch levels
  - No drilling studs
- Vertical chases around every 4 ft
- Push Romex wire or use wire puller
  - No wire staples
- Use top of wall, door and window plates for chases
- Can specify unique chase locations
- Can use affordable blue plastic work boxes

N.T.S.

# 9 – Wall Hung Units

- Walls are manufactured straight
  - No shims required
- Use 50% more screws to OSB
- Put screws anywhere

# 10 - Callbacks

Fewer callbacks with SIPs

- Stucco less likely to crack
- No drywall nails/screws to pop
- No sticking windows and doors

# SIPs and Energy

# Ratings: Energy Star vs. HERS

Most rating programs have a SIPs option

- SIP house rates better than a stick-framed house
- Some rating programs require a modified R value

## Energy Star

- Federal EPA program
- Minimum standards for a home
- Inspectors have checklists to verify requirements

## HERS (Home Energy Rating System)

- National (not federal) rating system by RESNET
- Assigns a home a rating based on a 2006 home standard
- No minimum requirements
- Lower score = better

# Insulation

Insulation has a high impact on HERS rating

- 3 ratings:

## Lowest

- Most batt insulation

## Middle

- Most spray insulation
- Special Inspection

## Highest

- SIPs
- May not require an inspection

# Door Blower Test

- Determines tightness of home
- Energy Star does not require this for SIP structures
- HERS requires this – SIPs get top ratings

# Conclusion

# Conclusion

SIPs 101 – Introduction to Structural Insulated Panels

- Structural, energy smart, durable, fast construction

What Can Architects Do for SIPs?

- Streamline design for constructability

What Can SIPs Do for Architects?

- Options for style

10 Common SIP Structural Engineering Mistakes

- SIPs can be complicated with poor design or materials

Building a SIPs Structure

- Learn Best Practices to save the most time

SIPs and Energy

- Cost savings over building lifetime

Taking advantage of SIPs can significantly reduce project costs.

# Thank You!
